**PROCRIT® (epoetin alfa)**

**HIGHLIGHTS OF PRESCRIBING INFORMATION**

These highlights do not include all the information needed to use PROCRIT safely and effectively. See full prescribing information for PROCRIT.

**PROCRIT® (epoetin alfa) injection, for intravenous or subcutaneous use**

*Initial U.S. Approval: 1989*

**WARNING: ESAs INCREASE THE RISK OF DEATH, MYOCARDIAL INFARCTION, STROKE, VENOUS THROMBOEMBOLISM, THROMBOSIS OF VASCULAR ACCESS AND TUMOR PROGRESSION OR RECURRENCE**

See full prescribing information for complete boxed warning.

**Chronic Kidney Disease:**

- In controlled trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 g/dL (5.1).
- No trial has identified a hemoglobin target level, ESA dose, or dosing strategy that does not increase these risks (2.2).
- Use the lowest PROCRIT dose sufficient to reduce the need for red blood cell (RBC) transfusions (5.1).

**Cancer:**

- ESAs shortened overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of patients with breast, non-small cell lung, head and neck, lymphoid, and cervical cancers (5.2).
- Use the lowest dose to avoid RBC transfusions (2.4).
- Use ESAs only for anemia from myelosuppressive chemotherapy (1.3).
- ESAs are not indicated for patients receiving myelosuppressive chemotherapy when the anticipated outcome is cure (1.5).
- Discontinue following the completion of a chemotherapy course (2.4).

**PeriSurgery:**

- Due to increased risk of deep venous thrombosis (DVT), DVT prophylaxis is recommended (5.1).

**RECENT MAJOR CHANGES**

- Dosage and Administration, Patients with Chronic Kidney Disease (2.2) 9/2017
- Warnings and Precautions, Increased Mortality and/or Increased Risk of Tumor Progression or Recurrence in Patients With Cancer (5.2) 7/2018
- Warnings and Precautions, Severe Cutaneous Reactions (5.8) 9/2017
- Warnings and Precautions, Risk of Serious Adverse Reactions Due to Benzyl Alcohol Preservative (5.9) 9/2017

**INDICATIONS AND USAGE**

- Treatment of anemia due to:
  - Chronic Kidney Disease (CKD) in patients on dialysis and not on dialysis (1.1).
  - Zidovudine in patients with HIV-infection (1.2).
- The effects of concomitant myelosuppressive chemotherapy, and upon initiation, there is a minimum of two additional months of planned chemotherapy (1.3).
- Reduction of allogeneic RBC transfusions in patients undergoing elective, noncardiac, nonvascular surgery (1.4).

**Limitations of Use**

PROCRIT has not been shown to improve quality of life, fatigue, or patient well-being (1.5).

PROCRIT is not indicated for use:

- In patients with cancer receiving hormonal agents, biologic products, or radiotherapy, unless also receiving concomitant myelosuppressive chemotherapy (1.5).
- In patients with cancer receiving myelosuppressive chemotherapy when the anticipated outcome is cure (1.5).
- In patients with cancer receiving myelosuppressive chemotherapy in whom the anemia can be managed by transfusion (1.5).
- In patients scheduled for surgery who are willing to donate autologous blood (1.5).
- In patients undergoing cardiac or vascular surgery (1.5).
- As a substitute for RBC transfusions in patients who require immediate correction of anemia (1.5).

**DOSEAGE AND ADMINISTRATION**

- Evaluate iron status before and during treatment and maintain iron repletion. Correct or exclude other causes of anemia before initiating treatment (2.1).
- In pregnant women, lactating women, neonates, infants: Use only single-dose vials (2.1).
- In patients with CKD: Initial dose: 50 to 100 Units/kg 2 times weekly (adults) and 50 Units/kg 3 times weekly (pediatric patients). Individualize maintenance dose. Invasive route recommended for patients on hemodialysis (2.2).
- In patients on Zidovudine due to HIV-infection: 100 Units/kg 3 times weekly (2.3).
- In patients with Cancer on Chemotherapy: 40,000 Units weekly or 150 Units/kg 3 times weekly (adults); 600 Units/kg intravenously weekly (pediatric patients) ≥ 5 years) (2.4).
- In Surgery Patients: 300 Units/kg per day for 15 days or 600 Units/kg weekly (2.5).

**DOSES FORMS AND STRENGTHS**

- Injection
  - 2,000 Units/mL, 3,000 Units/mL, 4,000 Units/mL, 10,000 Units/mL, and 40,000 Units/mL in single-dose vials (3)
  - 20,000 Units/2 mL, 10,000 Units/mL and 20,000 Units/mL in multiple-dose vials containing benzyl alcohol (3)

**CONTRAINdications**

- Uncontrolled hypertension (4)
- Pure red cell aplasia (PRCA) that begins after treatment with PROCRIT or other erythropoietin protein drugs (4)
- Serious allergic reactions to PROCRIT (4)
- Use of the multiple-dose vials containing benzyl alcohol in neonates, infants, pregnant women, and lactating women (4)

**WARNINGS AND PRECAUTIONS**

- Increased Mortality, Myocardial Infarction, Stroke, and Thromboembolism: Using ESAs to target a hemoglobin level of greater than 11 g/dL increases the risk of serious adverse cardiovascular reactions and has not been shown to provide additional benefit (5.1 and 14.1). Use caution in patients with coexistent cardiovascular disease and stroke (5.1).
- Increased Mortality and/or Increased Risk of Tumor Progression or Recurrence in Patients With Cancer (5.2).
- Hypertension: Control hypertension prior to initiating and during treatment with PROCRIT (5.3).
- Seizures: PROCRIT increases the risk for seizures in patients with CKD (5.4). Increase monitoring of these patients for changes in seizure frequency or premonitory symptoms (5.4).
- PRCA: If severe anemia and low reticulocyte count develop during PROCRIT treatment, withhold PROCRIT and evaluate for PRCA (5.6).
- Serious Allergic Reactions: Discontinue PROCRIT and manage reactions (5.7).
- Severe Cutaneous Reactions: Discontinue PROCRIT (5.8).

**ADVERSE REACTIONS**

- Patients with CKD: Adverse reactions in ≥ 5% of PROCRIT-treated patients in clinical studies were hypertension, arthralgia, muscle spasm, pyrexia, dizziness, medical device malfunction, vascular occlusion, and upper respiratory tract infection (6.1).
- Patients on Zidovudine due to HIV-infection: Adverse reactions in ≥ 5% of PROCRIT-treated patients in clinical studies were pyrexia, cough, rash, and injection site irritation (6.1).
- Patients with Cancer on Chemotherapy: Adverse reactions in ≥ 5% of PROCRIT-treated patients in clinical studies were nausea, vomiting, myalgia, arthralgia, somnolence, cough, weight decrease, leukopenia, bone pain, rash, hyperglycemia, insomnia, headache, depression, dysphagia, hypokalemia, and thrombosis (6.1).
- Surgery Patients: Adverse reactions in ≥ 5% of PROCRIT-treated patients in clinical studies were nausea, vomiting, pruritus, headache, injection site pain, chills, deep vein thrombosis, cough, and hypertension (6.1).

To report SUSPECTED ADVERSE REACTIONS, contact Janssen Products, LP at 1-800-JANSSEN (1-800-526-7736) or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

See 17 for PATIENT COUNSELING INFORMATION and Medication Guide.

Revised: 7/2018

FULL PRESCRIBING INFORMATION
WARNING: ESAs INCREASE THE RISK OF DEATH, MYOCARDIAL INFARCTION, STROKE, VENOUS THROMBOEMBOLISM, THROMBOSIS OF VASCULAR ACCESS AND TUMOR PROGRESSION OR RECURRENT

Chronic Kidney Disease:
- In controlled trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 g/dl. (see Warnings and Precautions [5.1]).
- No trial has identified a hemoglobin target level. ESA dose, or dosing strategy that does not increase these risks (seeDosage and Administration [2.2]).
- Use the lowest PROCRIT dose sufficient to reduce the need for red blood cell (RBC) transfusions (see Warnings and Precautions [5.1]).

Cancer:
- ESAs shortened overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of patients with breast, non-small cell lung, head and neck, lymphoid, and cervical cancers (see Warnings and Precautions [5.2]).
- To decrease these risks, as well as the risk of serious cardiovascular and thromboembolic reactions, use the lowest dose needed to avoid RBC transfusions (see Dosage and Administration [2.4]).
- Use ESAs only for anemia from myelosuppressive chemotherapy (see Indications and Usage [1.3]).
- ESAs are not indicated for patients receiving myelosuppressive chemotherapy when the anticipated outcome is cure (see Indications and Usage [1.5]).
- Discontinue following the completion of a chemotherapy course (see Dosage and Administration [2.4]).

Peri-surgery:
- Due to increased risk of Deep Venous Thrombosis (DVT), DVT prophylaxis is recommended (see Dosage and Administration [2.5], Warnings and Precautions [5.1]).

1 INDICATIONS AND USAGE
1.1 Anemia Due to Chronic Kidney Disease
PROCRIT is indicated for the treatment of anemia due to chronic kidney disease (CKD), including patients on dialysis and not on dialysis to decrease the need for red blood cell (RBC) transfusion.

1.2 Anemia Due to Zidovudine in Patients with HIV-infection
PROCRIT is indicated for the treatment of anemia due to zidovudine administered at ≤4200 mg/week in patients with HIV-infection with endogenous serum erythropoietin levels of ≤500 mUnits/mL.

1.3 Anemia Due to Chemotherapy in Patients With Cancer
PROCRIT is indicated for the treatment of anemia in patients with non-myeloid malignancies where anemia is due to the effect of concomitant myelosuppressive chemotherapy, and upon initiation, there is a minimum of two additional months of planned chemotherapy.

1.4 Reduction of Allogeneic Red Blood Cell Transfusions in Patients Undergoing Elective, Noncardiac, Nonvascular Surgery
PROCRIT is indicated to reduce the need for allogeneic RBC transfusions among patients with perioperative hemoglobin > 10 to ≤ 13 g/dL who are at high risk for perioperative blood loss from elective, noncardiac, nonvascular surgery. PROCRIT is not indicated for patients who are willing to donate autologous blood pre-operatively.

1.5 Limitations of Use
PROCRIT has not been shown to improve quality of life, fatigue, or patient well-being.
PROCRIT is not indicated for use:
- In patients with cancer receiving hormonal agents, biologic products, or radiotherapy, unless also receiving concomitant myelosuppressive chemotherapy.
- In patients with cancer receiving myelosuppressive chemotherapy when the anticipated outcome is cure.
- In patients with cancer receiving myelosuppressive chemotherapy in whom the anemia can be managed by transfusion.
- In patients scheduled for surgery who are willing to donate autologous blood.
- In patients undergoing cardiac or vascular surgery.
- As a substitute for RBC transfusions in patients who require immediate correction of anemia.

2 DOSAGE AND ADMINISTRATION
2.1 Important Dosing Information

Evaluation of Iron Stores and Nutritional Factors
Evaluate the iron status in all patients before and during treatment. Administer supplemental iron therapy when serum ferritin is less than 100 mcg/L or when serum transferrin saturation is less than 20%. The majority of patients with CKD will require supplemental iron during the course of ESA therapy.
Monitoring of Response to Therapy
Correct or exclude other causes of anemia (e.g., vitamin deficiency, metabolic or chronic inflammatory conditions, bleeding, etc.) before initiating PROCRIT. Following initiation of therapy and after each dose adjustment, monitor hemoglobin weekly until the hemoglobin level is stable and sufficient to minimize the need for RBC transfusion.

Selection of Formulation
In pregnant women, lactating women, neonates, and infants use only single-dose vials (the benzyl alcohol-free formulation) [see Contraindications (4) and Use in Specific Populations (8.1, 8.2, and 8.4)].

2.2 Patients with Chronic Kidney Disease
In controlled trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 g/dL. No trial has identified a hemoglobin target level, ESA dose, or dosing strategy that does not increase these risks. Individualize dosing and use the lowest dose of PROCRIT sufficient to reduce the need for RBC transfusions [see Warnings and Precautions (5.1)]. Physicians and patients should weigh the possible benefits of decreasing transfusions against the increased risks of death and other serious cardiovascular adverse reactions [see Boxed Warning and Clinical Studies (14)].

For all patients with CKD:
When initiating or adjusting therapy, monitor hemoglobin levels at least weekly until stable, then monitor at least monthly. When adjusting therapy consider hemoglobin rate of rise, rate of decline, ESA responsiveness and hemoglobin variability. A single hemoglobin excursion may not require a dosing change.
• Do not increase the dose more frequently than once every 4 weeks. Decreases in dose can occur more frequently. Avoid frequent dose adjustments.
• If the hemoglobin rises rapidly (e.g., more than 1 g/dL in any 2-week period), reduce the dose of PROCRIT by 25% or more as needed to reduce rapid responses.
• For patients who do not respond adequately, if the hemoglobin has not increased by more than 1 g/dL after 4 weeks of therapy, increase the dose by 25%.
• For patients who do not respond adequately over a 12-week escalation period, increasing the PROCRIT dose further is unlikely to improve response and may increase risks. Use the lowest dose that will maintain a hemoglobin level sufficient to reduce the need for RBC transfusions. Evaluate other causes of anemia. Discontinue PROCRIT if responsiveness does not improve.

For adult patients with CKD on dialysis:
• Initiate PROCRIT treatment when the hemoglobin level is less than 10 g/dL.
• If the hemoglobin level approaches or exceeds 11 g/dL, reduce or interrupt the dose of PROCRIT.
• The recommended starting dose for adult patients is 50 to 100 Units/kg 3 times weekly intravenously or subcutaneously. The intravenous route is recommended for patients on hemodialysis.

For adult patients with CKD not on dialysis:
• Consider initiating PROCRIT treatment only when the hemoglobin level is less than 10 g/dL and the following considerations apply:
  • The rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion and.
  • Reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal
• If the hemoglobin level exceeds 10 g/dL, reduce or interrupt the dose of PROCRIT, and use the lowest dose of PROCRIT sufficient to reduce the need for RBC transfusions.
• The recommended starting dose for adult patients is 50 to 100 Units/kg 3 times weekly intravenously or subcutaneously.

For pediatric patients with CKD:
• Initiate PROCRIT treatment only when the hemoglobin level is less than 10 g/dL.
• If the hemoglobin level approaches or exceeds 12 g/dL, reduce or interrupt the dose of PROCRIT.
• The recommended starting dose for pediatric patients (ages 1 month or older) is 50 Units/kg 3 times weekly intravenously or subcutaneously.

When treating patients who have chronic kidney disease and cancer, physicians should refer to Warnings and Precautions (5.1 and 5.2).

2.3 Zidovudine-treated Patients with HIV-infection
Starting Dose
The recommended starting dose in adults is 100 Units/kg as an intravenous or subcutaneous injection 3 times per week.

Dose Adjustment
• If hemoglobin does not increase after 8 weeks of therapy, increase PROCRIT dose by approximately 50 to 100 Units/kg at 4- to 8-week intervals until hemoglobin reaches a level needed to avoid RBC transfusions or 300 Units/kg.
• Withhold PROCRIT if hemoglobin exceeds 12 g/dL. Resume therapy at a dose 25% below the previous dose when hemoglobin declines to less than 11 g/dL.
• Discontinue PROCRIT if an increase in hemoglobin is not achieved at a dose of 300 Units/kg for 8 weeks.

2.4 Patients on Cancer Chemotherapy
Initiate PROCRIT in patients on cancer chemotherapy only if the hemoglobin is less than 10 g/dL, and if there is a minimum of two additional months of planned chemotherapy.
Use the lowest dose of PROCRIT necessary to avoid RBC transfusions.

Recommended Starting Dose
Adults:
• 150 Units/kg subcutaneously 3 times per week until completion of a chemotherapy course or
• 40,000 Units subcutaneously weekly until completion of a chemotherapy course.

Pediatric Patients (5 to 18 years):
• 600 Units/kg intravenously weekly until completion of a chemotherapy course.

Dose Reduction
Reduce dose by 25% if:
• Hemoglobin increases greater than 1 g/dL in any 2-week period or
• Hemoglobin reaches a level needed to avoid RBC transfusion.
Withhold dose if hemoglobin exceeds a level needed to avoid RBC transfusion. Reinitiate at a dose 25% below the previous dose when hemoglobin approaches a level where RBC transfusions may be required.

Dose Increase
After the initial 4 weeks of PROCRIT therapy, if hemoglobin increases by less than 1 g/dL and remains below 10 g/dL, increase dose to:
• 300 Units/kg three times per week in adults or
• 60,000 Units weekly in adults
• 900 Units/kg (maximum 60,000 Units) weekly in pediatric patients

After 8 weeks of therapy, if there is no response as measured by hemoglobin levels or if RBC transfusions are still required, discontinue PROCRIT.

2.5 Surgery Patients
The recommended PROCRIT regimen is:
• 300 Units/kg per day subcutaneously for 15 days total: administered daily for 10 days before surgery, on the day of surgery, and for 4 days after surgery.
• 600 Units/kg subcutaneously in 4 doses administered 21, 14, and 7 days before surgery and on the day of surgery.

Deep venous thrombosis prophylaxis is recommended during PROCRIT therapy [see Warnings and Precautions (5.1)].

2.6 Preparation and Administration
Do not shake. Do not use PROCRIT that has been shaken or frozen.
Protect vials from light.
Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration. Do not use any vials exhibiting particulate matter or discoloration.
Discard unused portions of PROCRIT in preservative-free vials. Do not re-enter preservative-free vials.
Store unused portions of PROCRIT in multiple-dose vials at 36°F to 46°F (2°C to 8°C). Discard 21 days after initial entry.
Do not dilute. Do not mix with other drug solutions except for admixing as described below:
Preservative-free PROCRIT from single-dose vials may be admixed in a syringe with bacteriostatic 0.9% sodium chloride injection, USP, with benzyl alcohol 0.9% (bacteriostatic saline) in a 1:1 ratio using aseptic technique at the time of administration. Do not mix PROCRIT with bacteriostatic saline when administering to pregnant women, lactating women, neonates, and infants [see Use in Specific Populations (8.1, 8.2, and 8.4)].

3. DOSAGE FORMS AND STRENGTHS

PROCRIT® (epoetin alfa)

Dose Adjustment
• If hemoglobin does not increase after 8 weeks of therapy, increase PROCRIT dose by approximately 50 to 100 Units/kg at 4- to 8-week intervals until hemoglobin reaches a level needed to avoid RBC transfusions or 300 Units/kg.
• Withhold PROCRIT if hemoglobin exceeds 12 g/dL. Resume therapy at a dose 25% below the previous dose when hemoglobin declines to less than 11 g/dL.
• Discontinue PROCRIT if an increase in hemoglobin is not achieved at a dose of 300 Units/kg for 8 weeks.

PROCRIT® (epoetin alfa)

Dose Reduction
Reduce dose by 25% if:
• Hemoglobin increases greater than 1 g/dL in any 2-week period or
• Hemoglobin reaches a level needed to avoid RBC transfusion.
Withhold dose if hemoglobin exceeds a level needed to avoid RBC transfusion. Reinitiate at a dose 25% below the previous dose when hemoglobin approaches a level where RBC transfusions may be required.

Dose Increase
After the initial 4 weeks of PROCRIT therapy, if hemoglobin increases by less than 1 g/dL and remains below 10 g/dL, increase dose to:
• 300 Units/kg three times per week in adults or
• 60,000 Units weekly in adults
• 900 Units/kg (maximum 60,000 Units) weekly in pediatric patients

After 8 weeks of therapy, if there is no response as measured by hemoglobin levels or if RBC transfusions are still required, discontinue PROCRIT.

2.5 Surgery Patients
The recommended PROCRIT regimens are:
• 300 Units/kg per day subcutaneously for 15 days total: administered daily for 10 days before surgery, on the day of surgery, and for 4 days after surgery.
• 600 Units/kg subcutaneously in 4 doses administered 21, 14, and 7 days before surgery and on the day of surgery.

Deep venous thrombosis prophylaxis is recommended during PROCRIT therapy [see Warnings and Precautions (5.1)].

2.6 Preparation and Administration
Do not shake. Do not use PROCRIT that has been shaken or frozen.
Protect vials from light.
Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration. Do not use any vials exhibiting particulate matter or discoloration.
Discard unused portions of PROCRIT in preservative-free vials. Do not re-enter preservative-free vials.
Store unused portions of PROCRIT in multiple-dose vials at 36°F to 46°F (2°C to 8°C). Discard 21 days after initial entry.
Do not dilute. Do not mix with other drug solutions except for admixing as described below:
Preservative-free PROCRIT from single-dose vials may be admixed in a syringe with bacteriostatic 0.9% sodium chloride injection, USP, with benzyl alcohol 0.9% (bacteriostatic saline) in a 1:1 ratio using aseptic technique at the time of administration. Do not mix PROCRIT with bacteriostatic saline when administering to pregnant women, lactating women, neonates, and infants [see Use in Specific Populations (8.1, 8.2, and 8.4)].

3. DOSAGE FORMS AND STRENGTHS

Injection:
• 2,000 Units/mL, 3,000 Units/mL, 4,000 Units/mL, 10,000 Units/mL, and 40,000 Units/mL of PROCRIT as a clear and colorless liquid in single-dose vials
• 20,000 Units/2 mL (10,000 Units/mL) and 20,000 Units/mL of PROCRIT as a clear and colorless liquid in multiple-dose vials (contains benzyl alcohol)
4 CONTRAINDICATIONS

PROCRIT® is contraindicated in patients with:

- Uncontrolled hypertension [see Warnings and Precautions (5.3)]
- Pure red cell aplasia (PRCA) that begins after treatment with PROCRIT® or other erythropoietin protein drugs [see Warnings and Precautions (5.6)]
- Serious allergic reactions to PROCRIT® [see Warnings and Precautions (5.7)]

PROCRIT® from multiple-dose vials contains benzyl alcohol and is contraindicated in:

- Neonates, infants, pregnant women, and lactating women [see Use in Specific Populations (8.1, 8.2, 8.4)].

5 WARNINGS AND PRECAUTIONS

5.1 Increased Mortality, Myocardial Infarction, Stroke, and Thromboembolism

- In controlled clinical trials of patients with CKD comparing higher hemoglobin levels (13 - 14 g/dL) to lower targets (9 - 11.5 g/dL), PROCRIT® and other ESAs increased the risk of death, myocardial infarction, stroke, congestive heart failure, thrombosis of hemodialysis vascular access, and other thromboembolic events in the higher target groups.

- Using ESAs to target a hemoglobin level of greater than 11 g/dL increases the risk of serious adverse cardiovascular reactions and has not been shown to provide additional benefit [see Clinical Studies (14.1)]. Use caution in patients with coexisting cardiovascular disease and stroke [see Dosage and Administration (2.2)]. Patients with CKD and an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. A rate of hemoglobin rise of greater than 1 g/dL over 2 weeks may contribute to these risks.

- In controlled clinical trials of patients with cancer, PROCRIT® and other ESAs increased the risks for death and serious adverse cardiovascular reactions. These adverse reactions included myocardial infarction and stroke.

- In controlled clinical trials, ESAs increased the risk of death in patients undergoing coronary artery bypass graft surgery (CABG) and the risk of deep venous thrombosis (DVT) in patients undergoing orthopedic procedures.

The design and overall results of the 3 large trials comparing higher and lower hemoglobin targets are shown in Table 1.

Patients Having Surgery

An increased incidence of deep venous thrombosis (DVT) in patients receiving epoetin alfa undergoing surgical orthopedic procedures was demonstrated [see Adverse Reactions (6.1)]. In a randomized, controlled study, 680 adult patients, not receiving prophylactic anticoagulation and undergoing spinal surgery, were randomized to 4 doses of 600 Units/kg epoetin alfa (7, 14, and 21 days before surgery, and the day of surgery) and standard of care (SOC) treatment (n=340) or SOC treatment alone (n=340). A higher incidence of DVTs, determined by either color flow duplex imaging or by clinical symptoms, was observed in the epoetin alfa group (16.4%) compared with the SOC group (7.2%). In addition to the 23 patients with DVTs included in the primary analysis, 19 of 23 patients (n=500) experienced 1 other thromboembolic event (TVE) each (12 [3.5%] in the epoetin alfa group and 7 [2.1%] in the SOC group). Deep venous thrombosis prophylaxis is strongly recommended when ESAs are used for the reduction of alloimmune RBC transfusions in surgical patients [see Dosage and Administration (2.9)].

Increased mortality was observed in a randomized, placebo-controlled study of PROCRIT® in adult patients who were undergoing CABG surgery (7 deaths in 126 patients randomized to PROCRIT® versus no deaths among 56 patients receiving placebo). Four of these deaths occurred during the period of study drug administration and all 4 deaths were associated with thrombotic events.

5.2 Increased Mortality and/or Increased Risk of Tumor Progression or Recurrence in Patients With Cancer

ESAs resulted in decreased locoregional control/progression-free survival (PFS) and/or overall survival (OS) [see Table 2].
Adverse effects on PFS and/or OS were observed in studies of patients receiving chemotherapy for breast cancer (Studies 1, 2, and 4), lymphoid malignancy (Study 3), and cervical cancer (Study 5), in patients with advanced head and neck cancer receiving radiation therapy (Studies 6 and 7); and in patients with non-small cell lung cancer or various malignancies who were not receiving chemotherapy or radiotherapy (Studies 8 and 9).

*Q1=25th percentile, Q3=75th percentile

This study did not include a defined hemoglobin target. Doses were titrated to achieve and maintain the lowest hemoglobin level sufficient to avoid transfusion and not to exceed 12 g/dL.

Decreased Overall Survival

Study 2 was described in the previous section (see Warnings and Precautions [5.1]). Mortality at 4 months (8.7% vs. 3.4%) was significantly higher in the epoetin alfa arm. The most common investigator- attributed cause of death within the first 4 months was disease progression; 28 of 41 deaths in the epoetin alfa arm and 13 of 16 deaths in the placebo arm were attributed to disease progression. Investigator- assessed response progression was not different between the 2 groups. Survival at 12 months was significantly lower in the epoetin alfa arm (70% vs. 76%; HR 1.37, 95% CI: 1.07, 1.75; p=0.012).

Study 3 was a randomized, double-blind study (darbepoetin alfa vs. placebo) conducted in 344 anemic patients with lymphoid malignancy receiving chemotherapy. With a median follow- up of 29 months, overall mortality rates were significantly higher among patients randomized to darbepoetin alfa as compared to placebo (HR 1.36, 95% CI: 1.02, 1.82).

Study 8 was a multicenter, randomized, double-blind study (epoetin alfa vs. placebo) in which patients with advanced non-small cell lung cancer receiving only palliative radiotherapy or no active therapy were treated with epoetin alfa to achieve and maintain hemoglobin levels between 12 and 14 g/dL. Following an interim analysis of 70 patients (planned accrual 280 patients), a significant difference in survival in favor of the patients in the placebo arm of the study was observed (median survival 63 vs. 129 days; HR 1.84; p=0.04).

Study 9 was a randomized, double-blind study (darbepoetin alfa vs. placebo) in 989 anemic patients with active malignant disease, neither receiving nor planning to receive chemotherapy or radiation therapy. There was no evidence of a statistically significant reduction in proportion of patients receiving RBC transfusions. The median survival was shorter in the darbepoetin alfa treatment group than in the placebo group (8 months vs. 10.8 months; HR 1.30, 95% CI: 1.07, 1.57).

Decreased Progression-free Survival and Overall Survival

Study 1 was a randomized, open-label, multicenter study in 2,098 anemic women with metastatic breast cancer, who received first line or second line chemotherapy. This was a noninferiority study designed to rule out a 15% risk increase in tumor progression or death of epoetin alfa plus standard of care (SOC) as compared with SOC alone. At the time of clinical data cutoff, the median progression free survival (PFS) per investigator assessment of disease progression was 7.4 months in each arm (HR 1.09, 95% CI: 0.99, 1.20), indicating the study objective was not met. There were more deaths from disease progression in the epoetin alfa plus SOC arm (59% vs. 56%) and more thrombotic vascular events in the epoetin alfa plus SOC arm (3% vs. 1%). At the final analysis, 1,653 deaths were reported (79.8% subjects in the epoetin alfa plus SOC group and 77.8% subjects in the SOC group). Median overall survival in the epoetin alfa plus SOC group was 17.8 months compared with 18.0 months in the SOC alone group (HR 1.07, 95% CI: 0.97, 1.18).

Study 4 was a randomized, open-label, controlled, factorial design study in which darbepoetin alfa was administered to prevent anemia in 733 women receiving neoadjuvant breast cancer treatment. A final analysis was performed after a median follow-up of approximately 3 years. The 3-year survival rate was lower (86% vs. 90%; HR 1.42, 95% CI: 0.93, 2.18) and the 3-year relapse-free survival rate was lower (72% vs. 78%; HR 1.32, 95% CI: 0.99, 1.79) in the darbepoetin alfa-treatment arm compared to the control arm.

Study 5 was a randomized, open-label, controlled study that enrolled 114 of a planned 460 cervical cancer patients receiving chemotherapy and radiotherapy. Patients were randomized to receive epoetin alfa to maintain hemoglobin between 12 and 14 g/dL or to RBC transfusion support as needed. The study was terminated prematurely due to an increase in thromboembolic adverse reactions in epoetin alfa-treated patients compared to control (19% vs. 9%). Both local recurrence (21% vs. 20%) and distant recurrence (12% vs. 7%) were more frequent in epoetin alfa-treated patients compared to control. Progression-free survival at 3 years was lower in the epoetin alfa-treatment group compared to control (59% vs. 62%; HR 1.06, 95% CI: 0.58, 1.91). Overall survival at 3 years was lower in the epoetin alfa-treatment group compared to control (61% vs. 71%; HR 1.28, 95% CI: 0.68, 2.42).

Study 6 was a randomized, placebo-controlled study in 351 head and neck cancer patients whose epoetin alfa-treated arm was administered to achieve target hemoglobins ≥ 14 and ≥ 15 g/dL for women and men, respectively. Locoregional progression-free survival was significantly shorter in patients receiving epoetin alfa beta (HR 1.62, 95% CI: 1.22, 2.14; p=0.0008) with medians of 406 days and 745 days in the epoetin beta and placebo arms, respectively. Overall survival was significantly shorter in patients receiving epoetin beta (HR 1.39, 95% CI: 1.05, 1.84; p=0.02).

Decreased Locoregional Control

Study 7 was a randomized, open-label, controlled study conducted in 522 patients with primary squamous cell carcinoma of the head and neck receiving radiation therapy alone (no chemotherapy) who were randomized to receive darbepoetin alfa to maintain hemoglobin levels of 14 to 15.5 g/dL or no darbepoetin alfa. An interim analysis performed on 484 patients demonstrated that locoregional control at 5 years was significantly shorter in patients receiving darbepoetin alfa (HR 1.44, 95% CI: 1.06, 1.90; p=0.02). Overall survival was shorter in patients receiving darbepoetin alfa (HR 1.28, 95% CI: 0.88, 1.86; p=0.08).

5.3 Hypertension

PROCRIT is contraindicated in patients with uncontrolled hypertension. Following initiation and titration of PROCRIT, approximately 25% of patients on dialysis required institution of or increases in antihypertensive therapy; hypertension and encephalopathy and seizures have been reported in patients with CKD receiving PROCRIT. Appropriately control hypertension prior to initiation of and during treatment with PROCRIT. Reduce or withhold PROCRIT if blood pressure becomes difficult to control. Advise patients of the importance of compliance with antihypertensive therapy and dietary restrictions [see Patient Counseling Information (17)].

5.4 Seizures

PROCRIT increases the risk of seizures in patients with CKD. During the first several months following initiation of PROCRIT, monitor patients closely for premonitory neurologic symptoms. Advise patients to contact their healthcare practitioner for new-onset seizures, premonitory symptoms or change in seizure frequency.
5.5 Lack or Loss of Hemoglobin Response to PROCRIT

For lack or loss of hemoglobin response to PROCRIT, initiate a search for causative factors (e.g., iron deficiency, infection, inflammation, bleeding). If typical causes of lack or loss of hemoglobin response are excluded, evaluate for PRCA [see Warnings and Precautions (5.6)]. In the absence of PRCA, follow dosing recommendations for management of patients with an insufficient hemoglobin response to PROCRIT therapy [see Dosage and Administration (2.2)].

5.6 Pure Red Cell Aplasia

Cases of PRCA and of severe anemia, with or without other cytopenias that arise following the development of neutralizing antibodies to erythropoetin have been reported in patients treated with PROCRIT. This has been reported predominantly in patients with CKD receiving ESAs by subcutaneous administration. PRCA has also been reported in patients receiving ESAs for anemia related to hepatitis C treatment (an indication for which PROCRIT is not approved).

If severe anemia and low reticulocyte count develop during treatment with PROCRIT, withhold PROCRIT and evaluate patients for neutralizing antibodies to erythropoetin. Contact Janssen Products, LP at 1-800-JANSSEN (1-800-526-7736) to perform assays for binding and neutralizing antibodies. Permanently discontinue PROCRIT in patients who develop PRCA following treatment with PROCRIT or other erythropoietin protein drugs. Do not switch patients to other ESAs.

5.7 Serious Allergic Reactions

Serious allergic reactions, including anaphylactic reactions, angioedema, bronchospasm, skin rash, and urticaria may occur with PROCRIT. Immediately and permanently discontinue PROCRIT and administer appropriate therapy if a serious allergic or anaphylactic reaction occurs.

5.8 Severe Cutaneous Reactions

Blistering and skin exfoliation reactions including Erythema multiforme and Stevens-Johnson Syndrome (SJS)/Toxic Epidermal Necrolysis (TEN), have been reported in patients treated with ESAs (including PROCRIT) in the postmarketing setting. Discontinue PROCRIT therapy immediately if a severe cutaneous reaction, such as SJS/TEN, is suspected.

5.9 Risk of Serious Adverse Reactions Due to Benzyl Alcohol Preservative

PROCRIT from multiple-dose vials contains benzyl alcohol and is contraindicated for use in neonates, infants, pregnant women, and lactating women [see Contraindications (4)]. In addition, do not mix PROCRIT with bacteriostatic saline (which also contains benzyl alcohol) when administering PROCRIT to these patient populations [see Dosage and Administration (2.1)].

Serious and fatal reactions including “gassing syndrome” can occur in neonates and infants treated with benzyl alcohol–preserved drugs, including PROCRIT multiple-dose vials. The “gassing syndrome” is characterized by central nervous system depression, metabolic acidosis, and gasping respirations. There is a potential for similar risks to fetuses and infants exposed to benzyl alcohol in utero or in breast-fed milk, respectively. PROCRIT multiple-dose vials contain 11 mg of benzyl alcohol per mL. The minimum amount of benzyl alcohol at which serious adverse reactions may occur is not known [see Use in Specific Populations (8.1, 8.2, and 8.4)].

5.10 Risk of Infectious Diseases Due to Albumin (Human) Content

PROCRIT contains albumin, a derivative of human blood [see Description (11)]. Based on effective donor screening and product manufacturing processes, it carries an extremely remote risk for transmission of viral diseases. A theoretical risk for transmission of Creutzfeldt-Jakob disease (CJD) also is considered extremely remote. No cases of transmission of viral diseases or CJD have ever been identified for albumin.

5.11 Dialysis Management

Patients may require adjustments in their dialysis prescriptions after initiation of PROCRIT. Patients receiving PROCRIT may require increased anticoagulation with heparin to prevent clotting of the extracorporeal circuit during hemodialysis.

6 ADVERSE REACTIONS

The following serious adverse reactions are discussed in greater detail in other sections of the label: • Increased Mortality, Myocardial Infarction, Stroke, and Thromboembolism [see Warnings and Precautions (5.1)] • Increased mortality and/or increased risk of tumor progression or recurrence in Patients With Cancer [see Warnings and Precautions (5.2)] • Hypertension [see Warnings and Precautions (5.3)] • Seizures [see Warnings and Precautions (5.4)] • PRCA [see Warnings and Precautions (5.6)] • Serious allergic reactions [see Warnings and Precautions (5.7)] • Severe Cutaneous Reactions [see Warnings and Precautions (5.8)]

6.1 Clinical Trial Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of other drugs and may not reflect the rates observed in practice.

Patients with Chronic Kidney Disease

Adul t Patients

Three double-blind, placebo-controlled studies, including 244 patients with CKD on dialysis, were used to identify the adverse reactions to PROCRIT. In these studies, the mean age of patients was 48 years (range: 20 to 80 years). One hundred and thirty-nine (56%) patients were men. The racial distribution was as follows: 177 (73%) patients were white, 48 (20%) patients were black, 4 (2%) patients were Asian, 12 (5%) patients were other, and racial information was missing for 3 (1%) patients. Two double-blind, placebo-controlled studies, including 210 patients with CKD on dialysis, were used to identify the adverse reactions to PROCRIT. In these studies, the mean age of patients was 57 years (range: 24 to 79 years). One hundred and twenty-one (59%) patients were men. The racial distribution was as follows: 164 (78%) patients were white, 38 (18%) patients were black, 3 (1%) patients were Asian, 3 (1%) patients were other, and racial information was missing for 2 (1%) patients.

The adverse reactions with a reported incidence of ≥ 5% in PROCRIT-treated patients and that occurred at a ≥ 1% higher frequency than in placebo-treated patients are shown in the table below:

Table 3: Adverse Reactions in Patients With CKD on Dialysis

</table>

An additional serious adverse reaction that occurred in less than 5% of epoetin alfa-treated dialysis patients and greater than placebo was thrombosis (2.7% PROCRIT and 1% placebo) [see Warnings and Precautions (5.1)]. The adverse reactions with a reported incidence of ≥ 5% in PROCRIT-treated patients and that occurred at a ≥ 1% higher frequency than in placebo-treated patients are shown in the table below:

Table 4: Adverse Reactions in Patients With CKD Not on Dialysis

Additional serious adverse reactions that occurred in less than 5% of epoetin alfa-treated patients not on dialysis and greater than placebo were erythema (0.8% PROCRIT and 0% placebo) and myocardial infarction (0.6% PROCRIT and 0% placebo) [see Warnings and Precautions (5.1)].

Pediatric Patients

In pediatric patients with CKD on dialysis, the pattern of adverse reactions was similar to that found in adults.

Zidovudine-treated Patients with HIV-infection

A total of 297 zidovudine-treated patients with HIV-infection were studied in 4 placebo-controlled studies. A total of 144 (48%) patients were randomly assigned to receive PROCRIT and 153 (52%) patients were randomly assigned to receive placebo. PROCRIT was administered at doses between 100 and 200 Units/kg 3 times weekly subcutaneously for up to 12 weeks. For the combined PROCRIT treatment groups, a total of 141 (98%) men and 3 (2%) women between the ages of 24 and 64 years were enrolled. The racial distribution of the combined PROCRIT treatment groups was as follows: 129 (90%) white, 8 (6%) black, 1 (1%) Asian, and 6 (4%) other.

In double-blind, placebo-controlled studies of 3 months duration involving approximately 300 zidovudine-treated patients with HIV-infection, adverse reactions with an incidence of ≥ 1% in patients treated with PROCRIT were:

Surgery Patients

Four hundred sixty-one patients undergoing major orthopedic surgery were studied in a placebo-controlled study (S1) and a comparative dosing study (S2). A total of 358 patients were randomly assigned to receive PROCRIT and 103 (22%) patients were randomly assigned to receive placebo. PROCRIT was administered daily at a dose of 100 to 300 IU/kg subcutaneously for 15 days or at 600 IU/kg once weekly for 4 weeks.

For the combined PROCRIT treatment groups, a total of 90 (25%) and 268 (75%) women between the ages of 29 and 89 years were enrolled. The racial distribution of the combined PROCRIT treatment groups was as follows: 288 (80%) white, 64 (18%) black, 1 (<1%) Asian, and 5 (1%) other.

The adverse reactions with a reported incidence of ≥ 1% in PROCRIT-treated patients that occurred at a higher frequency than in placebo-treated patients are shown in the table above.

6.2 Postmarketing Experience

The following adverse reactions have been identified during post-marketing use of PROCRIT.

Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

- Seizures [see Warnings and Precautions (5.4)]
- PRCA [see Warnings and Precautions (5.6)]
- Serious allergic reactions [see Warnings and Precautions (5.7)]
- Injection site reactions, including irritation and pain
- Porphyria
- Severe Cutaneous Reactions [see Warnings and Precautions (5.8)]

6.3 Immunogenicity

As with all therapeutic proteins, there is a potential for immunogenicity. The detection of antibody formation is highly dependent on the sensitivity and specificity of the assay. Additionally, the observed incidence of antibody (including neutralizing antibody) positivity in an assay may be influenced by several factors, including assay methodology, sample handling, timing of sample collection, concomitant medications, and underlying disease. For these reasons, comparison of the incidence of antibodies to epoetin alfa with the incidence of antibodies to other products may be misleading.

Neutralizing antibodies to epoetin alfa that cross-react with endogenous erythropoietin and other ESAs can result in PRCA or severe anemia (with or without other cytopenias) [see Warnings and Precautions (5.6)].

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

PROCRIT from multiple-dose vials contains benzyl alcohol and is contraindicated in pregnant women [see Contraindications (4)]. When therapy with PROCRIT is needed during pregnancy, use a benzyl alcohol-free formulation (i.e., single-dose vial). Do not mix PROCRIT with bacteriostatic saline when administering to pregnant women because it contains benzyl alcohol [see Clinical Considerations] [see Dosage and Administration (2.1)].

The limited available data on PROCRIT use in pregnant women are insufficient to determine a drug-associated risk of adverse developmental outcomes. In animal reproductive and developmental toxicity studies, adverse fetal effects including embryo-fetal death, skeletal anomalies, and growth defects occurred when pregnant rats received epoetin alpha at doses approximating the clinical recommended starting doses (see Data). Consider the benefits and risks of PROCRIT single-dose vials for the mother and possible risks to the fetus when prescribing PROCRIT to a pregnant woman.

The estimated background risk of major birth defects and miscarriage for the indicated population is unknown. All pregnancies have a background risk of birth defect, loss, or other adverse outcomes. In the U.S. general population, the estimated background risks of major birth defects and miscarriage in clinically recognized pregnancies is 2-4% and 15-20%, respectively.
PROCRIT® (epoetin alfa)

Clinical Considerations

Fetal/Neonatal Adverse Reactions

The multiple-dose vials of PROCRIT contain benzyl alcohol. The preservative benzyl alcohol has been associated with serious adverse reactions and death when administered intravenously to neonates and infants [see Warnings and Precautions (5.9), Use in Specific Populations (8.4)]. There is a potential for similar risks to fetuses exposed to benzyl alcohol in utero.

Data

Human Data

There are reports of pregnant women with anemia alone or anemia associated with severe renal disease and other hematologic disorders who received PROCRIT. Polyhydramnios and intrauterine growth restriction were reported in women with chronic renal disease, which is associated with an increased risk for these adverse pregnancy outcomes. Due to the limited number of exposed pregnancies and multiple confounding factors (such as underlying maternal conditions, other maternal medications, and gestational timing of exposure), these published case reports and studies do not reliably estimate the frequency, presence or absence of adverse outcomes.

Animal Data

When rats received PROCRIT at doses greater than or equal to 100 Units/kg/day during mating and through early pregnancy (dosing stopped prior to organogenesis), there were slight increases of maternal toxicity (red limbs/pinna, focal splenic capsule toxicity, increased organ weights). This animal dose level of 100 Units/kg/day may approximate the clinical recommended starting dose, depending on the treatment indication. When pregnant rats and rabbits received intravenous doses of up to 500 mg/kg/day of PROCRIT only during organogenesis (gestational days 7 to 17 in rats and gestational days 6 to 18 in rabbits), no teratogenic effects were observed in the offspring. The offspring (F1 generation) of the treated rats were observed postnatally; rats from the F1 generation reached maturity and were mated; no PROCRIT-related effects were apparent for their offspring (F2 generation fetuses).

When pregnant rats received PROCRIT at doses of 500 Units/kg/day late in pregnancy (after the period of organogenesis from day 17 of gestation through day 21 of lactation), pups exhibited decreased number of caudal vertebrae, decreased body weight gain, and delayed appearance of abdominal hair, eyelid opening, and ossifications (15% of maternal toxicity (red limbs/pinna, increased organ weights)). This animal dose level of 500 U/kg/day is approximately five times the clinical recommended starting dose depending on the patient’s treatment indication.

8.2 Lactation

Risk Summary

PROCRIT from multiple-dose vials contains benzyl alcohol and is contraindicated in lactating women [see Contraindications (4), Warnings and Precautions (5.9)].

Advise a lactating woman not to breastfeed for at least 2 weeks after the last dose. The preservative benzyl alcohol has been associated with serious adverse reactions and death when administered intravenously to neonates and infants [see Use in Specific Populations (8.4)]. There is a potential for similar risks to infants exposed to benzyl alcohol through human milk.

Do not mix PROCRIT with bacteriostatic saline containing benzyl alcohol, if administering PROCRIT to a lactating woman [see Dosage and Administration (2.1)].

There is no information regarding the presence of PROCRIT in human milk, the effects on the breastfed infant, or the effects on milk production. However, endogenous erythropoietin is present in human milk. Because many drugs are present in human milk, caution should be exercised when PROCRIT from single-dose vials is administered to a lactating woman.

8.4 Pediatric Use

The multiple-dose vials are formulated with benzyl alcohol and are contraindicated for use in neonates and infants [see Contraindications (4), Warnings and Precautions (5.9)]. When therapy with PROCRIT is needed in neonates and infants, use the single-dose vial, which is a benzyl alcohol-free formulation. Do not mix the single-dose vials with bacteriostatic saline when administering PROCRIT to neonates or infants because it contains benzyl alcohol [see Dosage and Administration (2.6)].

Serious adverse reactions including fatal reactions and the “gassing syndrome” occurred in premature neonates and infants in the neonatal intensive care unit who received drugs containing benzyl alcohol as a preservative. In these cases, benzyl alcohol dosages of 99 to 234 mg/kg/day produced high levels of benzyl alcohol and its metabolites in the blood and urine (blood levels of benzyl alcohol were 0.81 to 1.378 mmol/L). Additional adverse reactions included gradual neurological deterioration, seizures, intracranial hemorrhage, hematologic abnormalities, skin breakdown, hepatic and renal failure, hypotension, bradycardia, and cardiovascular collapse. Preterm, low birth weight infants may be more likely to develop these reactions because they may be less able to metabolize benzyl alcohol. The minimum amount of benzyl alcohol at which serious adverse reactions may occur is not known [see Warnings and Precautions (4.2)].

Pediatric Patients with CKD

PROCRIT is indicated in pediatric patients, ages 1 month to 18 years of age, for the treatment of anemia associated with CKD requiring dialysis. Safety and effectiveness in pediatric patients less than 1 month old have not been established [see Clinical Studies (14.1)].

Use of PROCRIT in pediatric patients with CKD not requiring dialysis is supported by efficacy in pediatric patients requiring dialysis. The mechanism of action of PROCRIT is the same for these two populations. Published literature also has reported the use of PROCRIT in pediatric patients with CKD not requiring dialysis. Dose-dependent increases in hemoglobin and hematocrit were observed with reductions in transfusion requirements.

The safety data from the pediatric studies and postmarketing reports are similar to those obtained from the studies of PROCRIT in adult patients with CKD [see Warnings and Precautions (5) and Adverse Reactions (6.1)]. Postmarketing reports do not indicate a difference in safety profiles in pediatric patients with CKD requiring dialysis and not requiring dialysis.

Pediatric Patients with Cancer on Chemotherapy

PROCRIT is indicated in patients 5 to 18 years old for the treatment of anemia due to concomitant myelosuppressive chemotherapy. Safety and effectiveness in pediatric patients less than 5 years of age have not been established [see Clinical Studies (14.3)]. The safety data from these studies are similar to those obtained from the studies of PROCRIT in adult patients with cancer [see Warnings and Precautions (5.1, 5.2) and Adverse Reactions (6.1)].

Pediatric Patients With HIV-infection Receiving Zidovudine

PROCRIT is indicated in patients 5 to 18 years old for the treatment of anemia due to concomitant myelosuppressive chemotherapy. Safety and effectiveness in pediatric patients less than 5 years of age have not been established [see Clinical Studies (14.3)]. The safety data from these studies are similar to those obtained from the studies of PROCRIT in adult patients with cancer [see Warnings and Precautions (5.1, 5.2) and Adverse Reactions (6.1)].

8.5 Geriatric Use

Of the 4,553 patients who received PROCRIT in the 6 studies for treatment of anemia due to CKD not receiving dialysis, 2726 (60%) were age 65 years and over, while rate of 8 (0.1%) were 75 years and over. Of the 757 patients who received PROCRIT in the 3 studies of CKD patients on dialysis, 381 (45%) were age 65 years and over, while rate of 10 (15%) were 75 years and over. No differences in safety or effectiveness were observed between geriatric and younger patients. Dose selection and adjustment for an elderly patient should be individualized to achieve and maintain the target hemoglobin [see Dosage and Administration (2)].

Among 778 patients enrolled in the 3 clinical studies of PROCRIT for the treatment of anemia due to concomitant chemotherapy, 419 received PROCRIT and 359 received placebo. Of the 419 who received PROCRIT, 247 (59%) were age 65 years and over, while 78 (19%) were 75 years and over. No overall differences in safety or effectiveness were observed between geriatric and younger patients. The dose requirements for PROCRIT in geriatric and younger patients within the 3 studies were similar.

Among 1,731 patients enrolled in the 3 clinical studies of PROCRIT for reduction of allogeneic RBC transfusions in patients undergoing elective surgery, 1,085 received PROCRIT and 646 received placebo or standard of care treatment. Of the 1,085 patients who received PROCRIT, 582 (54%) were age 65 years and over, while 245 (22%) were 75 years and over. No overall differences in safety or effectiveness were observed between geriatric and younger patients. The dose requirements for PROCRIT in geriatric and younger patients within the 3 studies were similar.

11 DESCRIPTION

Epoetin alfa is a 165-aa chain erythropoiesis-stimulating glycoprotein manufactured by recombinant DNA technology. It has a molecular weight of approximately 30,400 daltons and is produced by mammalian cells into which the human erythropoietin gene has been introduced. The product contains the identical amino acid sequence of isolated natural erythropoietin.
PROCRIT® (epoetin alfa) injection for intravenous or subcutaneous administration is formulated as a sterile, clear, colorless liquid in vials in multiple formulations. Single-dose vials, formulated with an isotonic sodium chloride/sodium citrate-buffered solution, are supplied in multiple strengths. Each single-dose 1 mL vial contains 2,000, 3,000, 4,000, or 10,000 Units of epoetin alfa, albumin (human) (2.5 mg), citric acid (0.06 mg), sodium chloride (5.9 mg), and sodium citrate (5.9 mg) in Water for Injection, USP (pH 6.9 ± 0.3). Single-dose, 2 mL vials contain 10,000 Units epoetin alfa, albumin (human) (2.5 mg), benzyl alcohol (1%), sodium chloride (8.2 mg), citric acid (0.11 mg), and sodium citrate (0.7 mg), sodium phosphate dibasic anhydride (1.8 mg), and sodium phosphate monobasic monohydrate (1.2 mg) in Water for Injection, USP (pH 6.9 ± 0.3). Multiple-dose, 1 mL vials contain 20,000 Units epoetin alfa, albumin (human) (2.5 mg), benzyl alcohol (1%), sodium chloride (8.2 mg), citric acid (0.11 mg), and sodium citrate (1.3 mg), per 1 mL of Water for Injection, USP (pH 6.1 ± 0.3).

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

PROCRIT stimulates erythropoiesis by the same mechanism as endogenous erythropoietin.

12.2 Pharmacodynamics

PROCRIT increases the reticulocyte count within 10 days of initiation, followed by increases in the RBC count, hemoglobin, and hematocrit, usually within 2 to 6 weeks. The rate of hemoglobin increase varies among patients and is dependent upon the dose of PROCRIT administered. For correction of anemia in hospitalized patients, a greater biologic response is not observed at doses exceeding 300 Units/kg 3 times weekly.

12.3 Pharmacokinetics

In adult and pediatric patients with CKD, the elimination half-life (t1/2) of plasma erythropoietin after intravenous administration of PROCRIT ranged from 4 to 13 hours. After subcutaneous administration, t1/2 was achieved within 5 to 24 hours. The t1/2 in adult patients with serum creatinine greater than 3 mg/dL was similar between those not on dialysis and those maintained on dialysis. The pharmacokinetic data indicate no apparent difference in PROCRIT t1/2 among adult patients above or below 65 years of age

A pharmacokinetic study comparing 150 Units/kg subcutaneous 3 times weekly to 40,000 Units subcutaneous weekly dosing regimen was conducted for 4 weeks in healthy subjects (n=12) and for 6 weeks in anemic cancer patients (n=32) receiving cyclic chemotherapy. There was no accumulation of serum erythropoietin after the 2 dosing regimens during the study period. The 40,000 Units weekly regimen had a higher tmax (3- to 7-fold), longer tmax (2- to 3-fold), higher AUC0-168 h (2- to 3-fold) of erythropoietin and lower clearance (CL) (50%) than the 150 Units/kg 3 times weekly regimen. In anemic cancer patients, the average t1/2 was similar (40 hours with range of 16 to 67 hours) after both dosing regimens. After the 150 Units/kg 3 times weekly dosing, the values of tmax and CL were similar (13.3 ± 12.4 vs. 14.2 ± 6.7 hours, 23.6 ± 9.5 mL/hr/kg vs. 26.5 ± 9.5 mL/hr/kg) between weeks 1 and 6 when patients were receiving chemotherapy (n=14) and week 3 when patients were not receiving chemotherapy (n=4). Differences were observed after the 40,000 Units weekly dosing with longer tmax (38 ± 18 hours) and lower CL (9.2 ± 4.7 mL/hr/kg) during week 1 when patients were receiving chemotherapy (n=18) compared with those (22 ± 4.5 hours, 13.9 ± 7.6 mL/hr/kg, respectively) during week 3 when patients were not receiving chemotherapy (n=7). The pharmacokinetic profile of PROCRIT in pediatric patients appeared similar to that of adults.

The pharmacokinetics of PROCRIT has not been studied in patients with HIV-infection.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

The carcinogenic potential of PROCRIT has not been evaluated.

PROCRIT was not mutagenic or clastogenic under the conditions tested: PROCRIT was negative in the in vitro bacterial reverse mutation assay (Ames test), in the in vitro mammalian cell gene mutation assay (the hypoxanthine-guanine phosphoribosyltransferase [EC 2.4.2.8] locus), in an in vitro chromosomal aberration assay in mammalian cells, and in the in vivo mouse micronucleus assay.

When administered intravenously to male and female rats prior to and during mating, and to females through the beginning of implantation (up to gestational day 7; dosing stopped prior to the beginning of organogenesis), doses of 100 and 500 Units/kg/day of PROCRIT caused slight increases in pre-implantation loss, post-implantation loss, and decreases in the incidence of live fetuses. It is not clear whether these effects reflect a drug effect on the uterine environment or on the conceptus. This animal dose level of 100 Units/kg/day approximates the clinical recommended starting dose, depending on the patient’s treatment indication, but may be lower than the clinical dose in patients whose doses have been adjusted.

14 CLINICAL STUDIES

14.1 Patients With Chronic Kidney Disease

Adult Patients on Dialysis

Patients with chronic kidney disease on dialysis: ESA effects on rates of transfusion. In clinical studies of patients with CKD on dialysis, PROCRIT increased hemoglobin levels and decreased the need for RBC transfusion. Overall, more than 95% of patients were RBC transfusion-independent after receiving PROCRIT for 3 months. In clinical studies at starting doses of 50 to 150 Units/kg 3 times weekly, adult patients responded with an average rate of hemoglobin rise as presented in Table 8.

The safety and efficacy of PROCRIT were evaluated in 13 clinical studies involving intravenous administration to a total of 1010 patients on dialysis with anemia. Overall, more than 90% of the patients treated with PROCRIT experienced improvement in hemoglobin concentrations. In the 3 largest of these clinical studies, the median maintenance dose necessary to maintain the hemoglobin between 10 to 12 g/dL was approximately 75 Units/kg 3 times weekly. More than 90% of patients were able to avoid RBC transfusions. In the largest US multicenter study, approximately 65% of the patients received doses of 100 Units/kg 3 times weekly or less to maintain their hemoglobin at approximately 11.7 g/dL. Almost 10% of patients received a dose of 25 Units/kg or less, and approximately 10% received a dose of more than 200 Units/kg 3 times weekly to maintain their hemoglobin at this level.

In the Normal Hematocrit Study, the yearly transfusion rate was 51.5% in the lower hemoglobin group (10 g/dL) and 32.4% in the higher hemoglobin group (14 g/dL).

Other ESA trials

In a 26-week, double-blind, placebo-controlled study, 118 patients on dialysis with an average hemoglobin of approximately 7 g/dL were randomized to either PROCRIT or placebo. By the end of the study, average hemoglobin increased to approximately 11 g/dL in the PROCRIT-treated patients and remained unchanged in patients receiving placebo. PROCRIT-treated patients experienced improvements in exercise tolerance and patient-reported physical functioning at month 2 that were maintained throughout the study.

A multicenter, unit-dose study was also conducted in 119 patients receiving peritoneal dialysis who self-administered PROCRIT subcutaneously. Patients responded to PROCRIT administered subcutaneously in a manner similar to patients receiving intravenous administration.

Pediatric Patients with CKD on Dialysis

The safety and efficacy of PROCRIT were studied in a placebo-controlled, randomized study of 113 pediatric patients with anemia (hemoglobin ≤ 9 g/dL) undergoing peritoneal dialysis or hemodialysis. The initial dose of PROCRIT was 50 Units/kg intravenously or subcutaneously 3 times weekly. The dose of study drug was titrated to achieve either a hemoglobin of 10 to 12 g/dL or an absolute increase in hemoglobin of 2 g/dL over baseline. At the end of the initial 12 weeks, a statistically significant rise in mean hemoglobin (3.1 g/dL vs. 0.3 g/dL) was observed only in the PROCRIT arm. The proportion of pediatric patients achieving a hemoglobin of 10 g/dL or an increase in hemoglobin of 2 g/dL over baseline, at any time during the first 12 weeks was higher in the PROCRIT arm (90% vs. 58%). Within 12 weeks of initiating PROCRIT therapy, 92.3% of the pediatric patients were RBC transfusion independent as compared to 65.4% who received placebo. Among patients who received 36 weeks of PROCRIT, hemodialysis patients received a higher median maintenance dose [167 Units/kg/week (n=28) vs. 76 Units/kg/week (n=38)] and took longer to achieve a hemoglobin of 10 to 12 g/dL (median time to response 69 days vs. 32 days) than patients undergoing peritoneal dialysis.

Adult Patients With CKD Not Requiring Dialysis

Four clinical studies were conducted in patients with CKD not on dialysis involving 181 patients treated with PROCRIT. These patients responded to PROCRIT therapy in a manner similar to that observed in patients on dialysis. Patients with CKD not on dialysis demonstrated a dose-dependent and sustained increase in hemoglobin with PROCRIT, and was administered by either an intravenous or subcutaneous route, with similar rates of rise of hemoglobin when PROCRIT was administered by either route.
PROCRIT® (epoetin alfa)

Patients with chronic kidney disease not on dialysis: ESA effects on rates of transfusion

In TREAT, a randomized, double-blind trial of 4038 patients with CKD and type 2 diabetes not on dialysis, a post-hoc analysis showed that the proportion of patients receiving RBC transfusions was lower in patients administered an ESA to target a hemoglobin of 13 g/dL compared to the control arm in which an ESA was administered intermittently if hemoglobin concentration decreased to less than 9 g/dL (15% versus 25%, respectively). In CHOIR, a randomized open-label study of 1432 patients with CKD not on dialysis, use of epoetin alfa to target a higher (13.5 g/dL) versus lower (11.3 g/dL) hemoglobin goal did not reduce the use of RBC transfusions. In each trial, no benefits occurred for the cardiovascular or end-stage renal disease outcomes. In each trial, the potential benefit of ESA therapy was offset by worse cardiovascular safety outcomes resulting in an unfavorable benefit-risk profile [see Warnings and Precautions (5.1)].

ESA Effects on rates of death and other serious cardiac adverse reactions

Three randomized outcome trials (Normal Hematocrit Study [NHS], Correction of Anemia with Epoetin Alfa in Chronic Kidney Disease [CHOIR], and Trial of Darbepoetin Alfa in Type 2 Diabetes and CKD [TREAT]) have been conducted in patients with CKD using EpoGen/PROCRIT/Aranesp to target higher vs. lower hemoglobin levels. Though these trials were designed to establish a cardiovascular or renal benefit of targeting higher hemoglobin levels, in all 3 studies, patients randomized to the higher hemoglobin target experienced worse cardiovascular outcomes and showed no reduction in progression to ESRD. In each trial, the potential benefit of ESA therapy was offset by worse cardiovascular safety outcomes resulting in an unfavorable benefit-risk profile [see Warnings and Precautions (5.1)].

14.2 Zidovudine-treated Patients With HIV-infection

The safety and efficacy of PROCRIT were evaluated in 4 placebo-controlled studies enrolling 297 anemic patients (hemoglobin < 10 g/dL) with HIV-infection receiving concomitant therapy with zidovudine. In the subgroup of patients (89/125 PROCRIT and 88/130 placebo) with pre-study endogenous serum erythropoietin levels ≤ 500 mUnits/mL, PROCRIT reduced the mean cumulative number of units of blood transfused per patient by approximately 40% as compared to the placebo group. Among those patients who required RBC transfusions at baseline, 43% of patients treated with PROCRIT versus 18% of placebo-treated patients were RBC transfusion independent during the second and third months of therapy. PROCRIT therapy also resulted in significant increases in hemoglobin in comparison to placebo. When examining the results according to the weekly dose of zidovudine received during month 3 of therapy, there was a statistically significant reduction (p < 0.003) in RBC transfusion requirements in patients treated with PROCRIT (n=51) compared to placebo-treated patients (n=54) whose mean weekly zidovudine dose was ≤ 4200 mg/week. Approximately 17% of the patients with endogenous serum erythropoietin levels ≤ 500 mUnits/mL receiving PROCRIT in doses from 100 to 200 Units/kg/3 times weekly achieved a hemoglobin of 12.7 g/dL without administration of RBC transfusions or significant reduction in zidovudine dose. In the subgroup of patients whose pre-study endogenous serum erythropoietin levels were > 500 mUnits/mL, PROCRIT therapy did not reduce RBC transfusion requirements or increase hemoglobin compared to the corresponding responses in placebo-treated patients.

14.3 Patients with Cancer on Chemotherapy

The safety and effectiveness of PROCRIT was assessed in 2 multicenter, randomized (1:1), placebo-controlled, double-blind studies. Study C1 and Study C2 and a pooled analysis of six additional randomized (1:1), multicenter, placebo-controlled, double-blind studies. All studies were conducted in patients with anemia due to concomitantly administered cancer chemotherapy. Study C1 enrolled 344 adult patients, Study C2 enrolled 222 pediatric patients, and the pooled analysis contained 131 patients randomized to epoetin alfa or placebo. In Studies C1 and C2, efficacy was demonstrated by a reduction in the proportion of patients who received an RBC transfusion, from week 5 through end of the study, with the last-known RBC transfusion status carried forward for patients who discontinued treatment. In the pooled analysis, efficacy was demonstrated by a reduction in the proportion of patients who received an RBC transfusion from week 5 through end of the study in the subset of patients who were remaining on therapy for 6 or more weeks.

Study C1

Study C1 was conducted in patients with anemia (hemoglobin < 11.5 g/dL for males, < 10.5 g/dL for females) with non-myeloid malignancies receiving myelosuppressive chemotherapy. Randomization was stratified by type of malignancy (lung vs. breast vs. other), concurrent radiation therapy planned (yes or no), and baseline hemoglobin (< 9 g/dL vs. ≥ 9 g/dL); patients were randomized to epoetin alfa 40,000 Units (n=174) or placebo (n=170) as a weekly subcutaneous injection commencing on the first day of the chemotherapy cycle.

Study C2

Study C2 was conducted in 222 patients with anemia, ages 5 to 18, receiving chemotherapy for the treatment of various childhood malignancies. Randomization was stratified by cancer type (solid tumors, Hodgkin’s disease, acute lymphocytic leukemia, vs. non-Hodgkin’s lymphoma); patients were randomized to receive epoetin alfa at 600 Units/kg maximum 40,000 Units (n=111) or placebo (n=111) as a weekly intravenous injection. Sixty-nine percent of patients were white, 55% were male, and the median age of patients was 12 years (range: 5 to 18 years). Two (2%) of placebo-treated patients and 3 (2%) of epoetin alfa-treated patients dropped out of the study prior to week 5. There were fewer RBC transfusions from week 5 through the end-of-study in epoetin-alfa treated patients (51% [57/111]) compared to placebo-treated patients (69% [77/111]). There was no evidence of an improvement in health-related quality of life, including no evidence of an effect on fatigue, energy, or strength in patients receiving PROCRIT as compared to those receiving placebo.

14.4 Surgery Patients

The safety and efficacy of PROCRIT were evaluated in a placebo-controlled, double-blind study (S1) enrolling 136 patients scheduled for major, elective orthopedic hip or knee surgery who were expected to require ≥ 2 units of blood and who were not able or willing to participate in an autologous blood donation program. Patients were stratified into 1 of 3 groups based on their pretreatment hemoglobin ≤ 10 g/dL (n=2), > 10 to ≤ 13 g/dL (n=98), and > 13 to ≤ 15 g/dL (n=218) and then assigned at random to receive 300 Units/kg PROCRIT, or placebo by subcutaneous injection for 10 days before surgery, on the day of surgery, and for 4 days after surgery. All patients received oral iron and a low-dose, postoperative warfarin regimen.

PROCRIT® (epoetin alfa)

Ninety-one percent of patients were white, 44% were male, and the median age of patients was 66 years (range: 20 to 88 years). The proportion of patients withdrawn from the study prior to week 5 was less than 10% for placebo-treated or epoetin-treated patients. Per protocol, the last available hemoglobin values from patients who dropped out were included in the efficacy analyses. Efficacy results are shown in Table 9.

Study C2

Study C2 was conducted in 222 patients with anemia, ages 5 to 18, receiving chemotherapy for the treatment of various childhood malignancies. Randomization was stratified by cancer type (solid tumors, Hodgkin’s disease, acute lymphocytic leukemia, vs. non-Hodgkin’s lymphoma); patients were randomized to receive epoetin alfa at 600 Units/kg maximum 40,000 Units (n=111) or placebo (n=111) as a weekly intravenous injection. Sixty-nine percent of patients were white, 55% were male, and the median age of patients was 12 years (range: 5 to 18 years). Two (2%) of placebo-treated patients and 3 (2%) of epoetin alfa-treated patients dropped out of the study prior to week 5. There were fewer RBC transfusions from week 5 through the end-of-study in epoetin-alfa treated patients (51% [57/111]) compared to placebo-treated patients (69% [77/111]). There was no evidence of an improvement in health-related quality of life, including no evidence of an effect on fatigue, energy, or strength in patients receiving PROCRIT as compared to those receiving placebo.

Pooled Analysis (Three Times Per Week Dosing)

The results of 6 studies of similar design and that randomized 131 patients to epoetin alfa or placebo were pooled to assess the safety and effectiveness of epoetin alfa. Patients were randomized to receive epoetin alfa at 150 Units/kg (n=83) or placebo (n=86), subcutaneously three times per week for 12 weeks in each study. Across all studies, 72 patients were treated with concomitant non-cisplatin-containing chemotherapy regimens and 59 patients were treated with concomitant cisplatin-containing chemotherapy regimens. Twelve patients (19%) in the epoetin alfa arm and 10 patients (15%) in the placebo-arm dropped out prior to week 6 and are excluded from efficacy analyses.

1 Limited to patients remaining on study beyond week 6 and includes only RBC transfusions during weeks 5-12.
2 Two-sided p < 0.05, unadjusted.
Treatment with PROCRIT 300 Units/kg significantly (p=0.024) reduced the risk of
allogeneic RBC transfusion in patients with a pretreatment hemoglobin of > 10 to
≤ 13 g/dL; 5/31 (16%) of patients treated with PROCRIT 300 Units/kg, 6/26 (23%)
of patients treated with PROCRIT 100 Units/kg, and 13/29 (45%) of placebo-treated
patients were transfused. There was no significant difference in the number of
patients transfused between PROCRIT (9% 300 Units/kg, 6% 100 Units/kg) and
placebo (13%) in the > 13 to ≤ 15 g/dL hemoglobin stratum. There were too few
patients in the ≤ 10 g/dL group to determine if PROCRIT is useful in this hemoglobin
strata. In the > 10 to ≤ 13 g/dL pretreatment stratum, the mean number of units
transfused per PROCRIT-treated patient (0.45 units blood for 300 Units/kg, 0.42 units
blood for 100 Units/kg) was less than the mean transfused per placebo-treated
patient (1.14 units) (overall p=0.028). In addition, mean hemoglobin, hematocrit,
and reticulocyte counts increased significantly during the presurgery period in
patients treated with PROCRIT.

PROCRIT was also evaluated in an open-label, parallel-group study (S2) enrolling
145 patients with a pretreatment hemoglobin level of ≥ 10 to ≤ 13 g/dL who were
scheduled for major orthopedic hip or knee surgery and who were not participating
in an autologous program. Patients were randomly assigned to receive 1 of 2
subcutaneous dosing regimens of PROCRIT (600 Units/kg once weekly for 3 weeks
prior to surgery and on the day of surgery, or 300 Units/kg once daily for 10 days
prior to surgery, on the day of surgery, and for 4 days after surgery). All patients
received oral iron and appropriate pharmacologic anticoagulation therapy.

From pretreatment to presurgery, the mean increase in hemoglobin in the
600 Units/kg weekly group (1.44 g/dL) was greater than that observed in the
300 Units/kg daily group. The mean increase in absolute reticulocyte count was
smaller in the weekly group (0.11 x 10^6/mm³) compared to the daily group (0.17 x
10^6/mm³). Mean hemoglobin levels were similar for the 2 treatment groups
throughout the postsurgical period.

The erythropoietic response observed in both treatment groups resulted in similar
RBC transfusion rates [11/69 (16%) in the 600 Units/kg weekly group and 14/71
(20%) in the 300 Units/kg daily group]. The mean number of units transfused per
patient was approximately 0.3 units in both treatment groups.

16 HOW SUPPLIED/STORAGE AND HANDLING

PROCRIT (epoetin alfa) injection is a sterile, clear, and colorless solution available as:
Preservative-free, single-dose vials (in citrate-buffered formulation): 2,000 Units/mL
(NDC 59676-302-01), 3,000 Units/mL (NDC 59676-303-01), 4,000 Units/mL (NDC 59676-
304-01), or 10,000 Units/mL (NDC 59676-310-01) supplied in cartons, each carton
containing six 1 mL single-dose vials.

Preservative-free, single-dose vials (in citrate-buffered formulation): 10,000 Units/mL
(NDC 59676-310-02) supplied in dispensing packs (tray) containing 25 single-dose
1 mL vials.

Preservative-free, single-dose vials (in phosphate-buffered formulation): 40,000
Units/mL (NDC 59676-340-01) supplied in dispensing packs containing four 1 mL
single-dose vials.

Preserved, multiple-dose vials: 20,000 Units/2mL (10,000 Units/mL) (NDC 59676-312-04)
supplied in dispensing packs containing four 2 mL multiple-dose vials.

Preserved, multiple-dose vials: 20,000 Units/mL (NDC 59676-320-04) supplied in
dispensing packs containing four 1 mL multiple-dose vials.

Store at 36°F to 46°F (2°C to 8°C). Do not freeze.

Do not shake. Do not use PROCRIT that has been shaken or frozen.

Store PROCRIT vials in the original carton until use to protect from light.

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide
and Instructions for Use).

Inform patients:

- Of the increased risks of mortality, serious cardiovascular reactions,
thromboembolic reactions, stroke, and tumor progression [see Warnings and
Precautions (5.1, 5.2)].
- To undergo regular blood pressure monitoring, adhere to prescribed anti-
hypertensive regimen and follow recommended dietary restrictions.
- To contact their healthcare provider for new-onset neurologic symptoms or
change in seizure frequency.
- Of the need to have regular laboratory tests for hemoglobin.
- Risks are associated with benzyl alcohol in neonates, infants, pregnant
women, and lactating women [see Use in Specific Populations (8.1, 8.2, 8.4)].

Instruct patients who self-administer PROCRIT of the:

- Importance of following the Instructions for Use.
- Dangers of reusing needles, syringes, or unused portions of single-dose vials.
- Proper disposal of used syringes, needles, and unused vials, and of the full
container.

© 2000 Janssen Pharmaceutical Companies
MEDICATION GUIDE
PROCRIT® (PRO−KRIT)
(epoetin alfa)

Read this Medication Guide:
• before you start PROCRIT.
• if you are told by your healthcare provider that there is new information about PROCRIT.
• if you are told by your healthcare provider that you may inject PROCRIT at home, read this Medication Guide each time you receive a new supply of medicine.

This Medication Guide does not take the place of talking to your healthcare provider about your medical condition or your treatment. Talk with your healthcare provider regularly about the use of PROCRIT and ask if there is new information about PROCRIT.

What is the most important information I should know about PROCRIT?

PROCRIT may cause serious side effects that can lead to death, including:

For people with cancer:
• Your tumor may grow faster and you may die sooner if you choose to take PROCRIT. Your healthcare provider will talk with you about these risks.

For all people who take PROCRIT, including people with cancer or chronic kidney disease:
• Serious heart problems, such as heart attack or heart failure, and stroke. You may die sooner if you are treated with PROCRIT to increase red blood cells (RBCs) to near the same level found in healthy people.
• Blood clots. Blood clots may happen at any time while taking PROCRIT. If you are receiving PROCRIT for any reason and you are going to have surgery, talk to your healthcare provider about whether or not you need to take a blood thinner to lessen the chance of blood clots during or following surgery. Blood clots can form in blood vessels (veins), especially in your leg (deep venous thrombosis or DVT). Pieces of a blood clot may travel to the lungs and block the blood circulation in the lungs (pulmonary embolus).

Call your healthcare provider or get medical help right away if you have any of these symptoms:
◦ Chest pain
◦ Trouble breathing or shortness of breath
◦ Pain in your legs, with or without swelling
◦ A cool or pale arm or leg
◦ Sudden confusion, trouble speaking, or trouble understanding others’ speech
◦ Sudden numbness or weakness in your face, arm, or leg, especially on one side of your body
◦ Sudden trouble seeing
◦ Sudden trouble walking, dizziness, loss of balance or coordination
◦ Loss of consciousness (fainting)
◦ Hemodialysis vascular access stops working

See “What are the possible side effects of PROCRIT?” below for more information.

If you decide to take PROCRIT, your healthcare provider should prescribe the smallest dose of PROCRIT that is necessary to reduce your chance of needing RBC transfusions.
What is PROCRIT?
PROCRIT is a prescription medicine used to treat anemia. People with anemia have a lower-than-normal number of RBCs. PROCRIT works like the human protein called erythropoietin to help your body make more RBCs. PROCRIT is used to reduce or avoid the need for RBC transfusions.

PROCRIT may be used to treat anemia if it is caused by:
- Chronic kidney disease (you may or may not be on dialysis).
- Chemotherapy that will be used for at least two months after starting PROCRIT.
- A medicine called zidovudine (AZT) used to treat HIV infection.

PROCRIT may also be used to reduce the chance you will need RBC transfusions if you are scheduled for certain surgeries where a lot of blood loss is expected.

If your hemoglobin level stays too high or if your hemoglobin goes up too quickly, this may lead to serious health problems which may result in death. These serious health problems may happen if you take PROCRIT, even if you do not have an increase in your hemoglobin level.

PROCRIT has not been proven to improve quality of life, fatigue, or well-being.

PROCRIT should not be used for treatment of anemia:
- If you have cancer and you will not be receiving chemotherapy that may cause anemia.
- If you have a cancer that has a high chance of being cured. Talk with your healthcare provider about the kind of cancer you have.
- If your anemia caused by chemotherapy treatment can be managed by RBC transfusion.
- In place of emergency treatment for anemia (RBC transfusions).

PROCRIT should not be used to reduce the chance you will need RBC transfusions if:
- You are scheduled for surgery on your heart or blood vessels.
- You are able and willing to donate blood prior to surgery.

It is not known if PROCRIT is safe and effective in treating anemia in children less than 1 month old who have chronic kidney disease and in children less than 5 years old who have anemia caused by chemotherapy.

Who should not take PROCRIT?
Do not take PROCRIT if you:
- Have cancer and have not been counseled by your healthcare provider about treatment with PROCRIT.
- Have high blood pressure that is not controlled (uncontrolled hypertension).
- Have been told by your healthcare provider that you have or have ever had a type of anemia called Pure Red Cell Aplasia (PRCA) that starts after treatment with PROCRIT or other erythropoietin protein medicines.
- Have had a serious allergic reaction to PROCRIT.

Do not give PROCRIT from multiple-dose vials to:
- Pregnant or breastfeeding women
- Babies

Before taking PROCRIT, tell your healthcare provider about all of your medical conditions, including if you:
- Have heart disease.
- Have high blood pressure.
- Have had a seizure (convulsion) or stroke.
- Receive dialysis treatment.
- Are pregnant or plan to become pregnant. It is not known if PROCRIT may harm your unborn baby. Talk to your healthcare provider about possible pregnancy and birth control choices that are right for you.
- Are breastfeeding or plan to breastfeed. It is not known if PROCRIT passes into breast milk.

Tell your healthcare provider about all the medicines you take, including prescription and over-the-counter medicines, vitamins, and herbal supplements.
How should I take PROCRIT?

- If you or your caregiver has been trained to give PROCRIT shots (injections) at home:
  - Be sure that you read, understand, and follow the “Instructions for Use” that come with PROCRIT.
  - Take PROCRIT exactly as your healthcare provider tells you to. Do not change the dose of PROCRIT unless told to do so by your healthcare provider.
  - Your healthcare provider will show you how much PROCRIT to use, how to inject it, how often it should be injected, and how to safely throw away the used vials, syringes, and needles.
  - If you miss a dose of PROCRIT, call your healthcare provider right away and ask what to do.
  - If you take more than the prescribed dose of PROCRIT, call your healthcare provider right away.
- During treatment with PROCRIT, continue to follow your healthcare provider’s instructions for diet and medicines.
- Have your blood pressure checked as instructed by your healthcare provider.

What are the possible side effects of PROCRIT?

PROCRIT may cause serious side effects, including:

- See "What is the most important information I should know about PROCRIT?"
- **High blood pressure.** High blood pressure is a common side effect of PROCRIT in people with chronic kidney disease. Your blood pressure may go up or be difficult to control with blood pressure medicine while taking PROCRIT. This can happen even if you have never had high blood pressure before. Your healthcare provider should check your blood pressure often. If your blood pressure does go up, your healthcare provider may prescribe new or more blood pressure medicine.

- **Seizures.** If you have any seizures while taking PROCRIT, get medical help right away and tell your healthcare provider.

- **Antibodies to PROCRIT.** Your body may make antibodies to PROCRIT. These antibodies can block or lessen your body’s ability to make RBCs and cause you to have severe anemia. Call your healthcare provider if you have unusual tiredness, lack of energy, dizziness, or fainting. You may need to stop taking PROCRIT.

- **Serious allergic reactions.** Serious allergic reactions can cause a skin rash, itching, shortness of breath, wheezing, dizziness and fainting because of a drop in blood pressure, swelling around your mouth or eyes, fast pulse, or sweating. If you have a serious allergic reaction, stop using PROCRIT and call your healthcare provider or get medical help right away.

- **Severe skin reactions.** Signs and symptoms of severe skin reactions with PROCRIT may include: skin rash with itching, blisters, skin sores, peeling, or areas of skin coming off. If you have any signs or symptoms of a severe skin reaction, stop using PROCRIT and call your healthcare provider or get medical help right away.

- **Dangers of using PROCRIT from multiple-dose vials in newborns, infants, and pregnant or breastfeeding women.** Do not use PROCRIT from multiple-dose vials in newborns, infants, pregnant or breastfeeding women because the PROCRIT in these vials contains benzyl alcohol. Benzyl alcohol has been shown to cause brain damage, other serious side effects, and death in newborn and premature babies. If you use PROCRIT from multiple-dose vials you should not breastfeed for at least 2 weeks after the last dose. PROCRIT that comes in single-dose vials does not contain benzyl alcohol. See “Who should not take PROCRIT?”

Common side effects of PROCRIT include:

- joint, muscle, or bone pain
- fever
- cough
- dizziness
- high blood sugar
- low potassium levels in the blood
- chills
- redness and pain at the PROCRIT injection site
- rash
- nausea
- vomiting
- blood vessel blockage
- low white blood cells
- trouble sleeping
- difficulty swallowing
- soreness of mouth
- itching
- headache
- respiratory infection
- weight decrease
- depression
- muscle spasm

These are not all of the possible side effects of PROCRIT. Your healthcare provider can give you a more complete list. Tell your healthcare provider about any side effects that bother you or that do not go away.

Call your doctor for medical advice about side effects. You may report side effects to FDA at 1-800-FDA-1088.
How should I store PROCRIT?

- Do not shake PROCRIT.
- Store PROCRIT vials in the carton it comes in to protect from light.
- Store PROCRIT in the refrigerator between 36°F to 46°F (2°C to 8°C).
- Do not freeze PROCRIT. Do not use PROCRIT that has been frozen.
- Throw away multiple-dose vials of PROCRIT no later than 21 days from the first day that you put a needle into the vial.
- Single-dose vials of PROCRIT should be used only one time. Throw the vial away after use even if there is medicine left in the vial.

Keep PROCRIT and all medicines out of the reach of children.

General information about PROCRIT

Medicines are sometimes prescribed for purposes other than those listed in a Medication Guide. Do not use PROCRIT for a condition for which it was not prescribed. Do not give PROCRIT to other people even if they have the same symptoms that you have. It may harm them. You can ask your healthcare provider or pharmacist for information about PROCRIT that is written for healthcare professionals.

What are the ingredients in PROCRIT?

Active ingredient: epoetin alfa

Inactive ingredients:
- Multiple-dose vials contain benzyl alcohol.
- All vials contain albumin (human), citric acid, sodium chloride, sodium citrate and Water for Injection.
- Single-dose vials containing 40,000 Units of PROCRIT also contain sodium phosphate dibasic anhydrate and sodium phosphate monobasic monohydrate.

Instructions for Use
PROCRIT® (PRO'−KRIT)
(epoetin alfa)

Use these Instructions for Use if you or your caregiver has been trained to give PROCRIT injections at home. Do not give yourself the injection unless you have received training from your healthcare provider. If you are not sure about giving the injection or you have questions, ask your healthcare provider for help.

Before reading these Instructions for Use, read the Medication Guide that comes with PROCRIT for the most important information you need to know.

When you receive your PROCRIT vial and syringes make sure that:

• The name PROCRIT appears on the carton and vial label.
• The expiration date on the vial label has not passed. Do not use a vial of PROCRIT after the expiration date on the label.
• The dose strength of the PROCRIT vial (number of Units per mL on the vial label) is the same as your healthcare provider prescribed.
• You understand what the dose strength of PROCRIT means. PROCRIT vials come in several dose strengths. For example, the dose strength may be described as 10,000 Units/mL on the vial label. This strength means that 10,000 Units of medicine are contained in each 1 mL (milliliter) of liquid. Your healthcare provider may also refer to a mL as a “cc.” One mL is the same as one “cc.”
• The PROCRIT liquid in the vial is clear and colorless. Do not use PROCRIT if the liquid in the vial looks discolored or cloudy, or if the liquid has lumps, flakes, or particles.
• The PROCRIT vial has a color cap on the top of the vial. Do not use a vial of PROCRIT if the color cap on the top of the vial has been removed or is missing.
• Use only the type of disposable syringe and needle that your healthcare provider has prescribed.
• Do not shake PROCRIT. Shaking could cause PROCRIT not to work. If you shake PROCRIT, the solution in the vial may look foamy and should not be used.
• Do not freeze PROCRIT. Do not use a vial of PROCRIT that has been frozen.
• Store PROCRIT in the refrigerator between 36°F to 46°F (2°C to 8°C).
• Keep PROCRIT away from light.
• Single-dose vials of PROCRIT should be used only one time. Throw the vial away after use even if there is medicine left in the vial.
• After removing a dose from the multidose vial, store the vial in the refrigerator (but not the freezer). Do not store the vial for more than 21 days.
• Throw away the multidose vial as directed by your healthcare provider:
  o if there is not enough medicine left in the multidose vial for another dose, or
  o if it has been more than 21 days since you first put a needle into the multidose vial.

How should I prepare for an injection of PROCRIT?
• Always keep an extra syringe and needle on hand.
• Follow your healthcare provider’s instructions on how to measure your dose of PROCRIT. This dose will be measured in Units per mL or cc (1 mL is the same as 1 cc). Use a syringe that is marked in tenths of mL (for example, 0.2 mL or 0.2 cc). Using the wrong syringe can lead to a mistake in your dose and you could inject too much or too little PROCRIT.

Only use disposable syringes and needles. Use the syringes and needles only one time and then throw them away as instructed by your healthcare provider.

What do I need to know about the different types of PROCRIT vials?
PROCRIT comes in two different types of vials.
• Single-dose Vials
• Multidose Vials

The multidose vial of PROCRIT contains the preservative benzyl alcohol. Benzyl alcohol has been shown to cause brain damage, other serious side effects, and death in newborn and premature babies. PROCRIT that comes in single-dose vials does not contain benzyl alcohol.

Important: Follow these instructions exactly to help avoid infections.

Preparing the dose:
1. Remove the vial of PROCRIT from the refrigerator. During this time, protect the solution from light.
2. Do not use a single-dose vial of PROCRIT more than one time.
3. Do not shake PROCRIT.
4. Gather the other supplies you will need for your injection (vial, syringe, alcohol wipes, cotton ball, and a puncture-proof container for throwing away the syringe and needle). See Figure 1.

5. Check the date on the PROCRIT vial to be sure that the drug has not expired.
6. Wash your hands well with soap and water before preparing the medicine. See Figure 2.

7. Flip off the protective color cap on the top of the vial. Do not remove the grey rubber stopper. Wipe the top of the grey rubber stopper with an alcohol wipe. See Figures 3 and 4.

8. Check the package containing the syringe. If the package has been opened or damaged, do not use that syringe. Throw away the syringe in the puncture-proof disposable container. If the syringe package is undamaged, open the package and remove the syringe.

9. Using a syringe and needle that has been recommended by your healthcare provider, carefully remove the needle cover. See Figure 5. Then draw air into the syringe by pulling back on the plunger. The amount of air drawn into the syringe should be equal to the amount (mL or cc) of the PROCRIT dose prescribed by your healthcare provider. See Figure 6.

10. With the vial on a flat work surface, insert the needle straight down through the grey rubber stopper of the PROCRIT vial. See Figure 7.

11. Push the plunger of the syringe down to inject the air from the syringe into the vial of PROCRIT. The air injected into the vial will allow PROCRIT to be easily withdrawn into the syringe. See Figure 7.

12. Keep the needle inside the vial. Turn the vial and syringe upside down. Be sure the tip of the needle is in the PROCRIT liquid. Keep the vial upside down. Slowly pull back on the plunger to fill the syringe with PROCRIT liquid to the number (mL or cc) that matches the dose your healthcare provider prescribed. See Figure 8.

13. Keep the needle in the vial. Check for air bubbles in the syringe. A small amount of air is harmless. Too large an air bubble will give you the wrong PROCRIT dose. To remove air bubbles, gently tap the syringe with your fingers until the air bubbles rise to the top of the syringe. Slowly push the plunger up to force the air bubbles out of the syringe. Keep the tip of the needle in the PROCRIT liquid. Pull the plunger back to the number on the syringe that matches your dose. Check again for air bubbles. If there are still air bubbles, repeat the steps above to remove them. See Figures 9 and 10.

14. Double-check that you have the correct dose in the syringe. Lay the vial down on its side with the needle still in it until after you have selected and prepared your site for injection.
Selecting and preparing the injection site:
PROCRIT can be injected into your body using two different ways (routes) as described below. Follow your healthcare provider’s instructions about how you should inject PROCRIT. In patients on hemodialysis, the intravenous (IV) route is recommended.

1. Subcutaneous Route:
   • PROCRIT can be injected directly into a layer of fat under your skin. This is called a subcutaneous injection. When giving subcutaneous injections, follow your healthcare provider’s instructions about changing the site for each injection. You may wish to write down the site where you have injected.
   • Do not inject PROCRIT into an area that is tender, red, bruised, hard, or has scars or stretch marks. Recommended sites for injection are shown in Figure 11 below, including:
     ◦ The outer area of the upper arms
     ◦ The abdomen (except for the 2-inch area around the navel)
     ◦ The front of the middle thighs
     ◦ The upper outer area of the buttocks
   • Clean the skin with an alcohol wipe where the injection is to be made. Be careful not to touch the skin that has been wiped clean. See Figure 12.
   • Double-check that the correct amount of PROCRIT is in the syringe.
   • Remove the prepared syringe and needle from the vial of PROCRIT and hold it in the hand that you will use to inject the medicine.

2. Intravenous Route:
   • PROCRIT can be injected in your vein through a special access port placed by your healthcare provider. This type of PROCRIT injection is called an intravenous (IV) injection. This route is usually for hemodialysis patients.
   • If you have a dialysis vascular access, make sure it is working by checking it as your healthcare provider has shown you. Be sure to let your healthcare provider know right away if you are having any problems, or if you have any questions.
   • Wipe off the venous port of the hemodialysis tubing with an alcohol wipe. See Figure 15.

   **Figure 11**

   **Figure 12**

   **Figure 13**

   **Figure 14**

   **Figure 15**
- Insert the needle of the syringe into the cleaned venous port and push the plunger all the way down to inject all the PROCRIT. See Figure 16.

![Figure 16](image)

- Remove the syringe from the venous port. Do not recap the needle.
- Dispose of the used syringe and needle as described below.

**How should I dispose of the vials, syringes, and needles?**

Do not reuse the single-dose vials, syringes, or needles. Throw away the vials, syringes, and needles as instructed by your healthcare provider or by following these steps:

- Do not throw the vials, syringes, or needles in the household trash or recycle.
- Do not put the needle cover back on the needle.
- Place all used needles and syringes in a puncture-proof disposable container with a lid. Do not use glass or clear plastic containers, or any container that will be recycled or returned to a store.
- Keep the puncture-proof disposable container out of the reach of children.
- When the puncture-proof disposable container is full, tape around the cap or lid to make sure the cap or lid does not come off. Throw away the puncture-proof disposable container as instructed by your healthcare provider. There may be special state and local laws for disposing of used needles and syringes. **Do not throw the puncture-proof disposable container in the household trash. Do not recycle.**

**Keep PROCRIT and all medicines out of reach of children.**

These Instructions for Use have been approved by the U.S. Food and Drug Administration.
